Asymptotics of Chebyshev of Second Kind

Since

$$\sin(n \pm 1)\theta = \sin n\theta \cos \theta \pm \cos n\theta \sin \theta$$

we have that

$$\sin(n+1)\theta + \sin(n-1)\theta = 2 \cos \theta (\sin n\theta)$$

If $f_n(\theta) = \frac{\sin(n+1)\theta}{\sin \theta}$, then $f_{-1} = 0$, $f_0 = 1$, and $f_{n+1} + f_{n-1} = (2 \cos \theta) f_n$.

Thus, by induction, $f_n(\theta)$ is a polynomial in $2 \cos \theta$ of degree n , i.e.,

$$f_n(\theta) = p_n(2 \cos \theta)$$

where

$$p_{n+1}(x) + p_{n-1}(x) = xp_n(x); \quad p_{-1} = 0, p_0 = 1$$

Thus, $\{p_n(x)\}_{n=0}^{\infty}$ are the orthonormal OPs with Jacobi parameters, $b_n \equiv 0$, $a_n \equiv 1$.

$x = 2 \cos \theta$ (leads to quadratic equation for $e^{i\theta}$) so

$$e^{\pm i\theta} = \frac{x}{2} \pm \sqrt{1 - \left(\frac{x}{2}\right)^2}$$

WARNING: I am very bad at calculations. Factors of $2, \pi$, etc., could be wrong.

Since $\sin(k\theta)$ are orthogonal for $\frac{d\theta}{2\pi}$, $f_n(\theta)$ are orthogonal for $\sin^2 \theta \frac{d\theta}{2\pi}$ (for normalization on $[0, 2\pi]$).

But $\theta \mapsto x = 2 \cos \theta$ is 2 to 1 from $[0, 2\pi]$ to $[-2, 2]$, so we want to look at $2 \sin^2 \theta \frac{d\theta}{2\pi}$ on $[0, \pi]$.

$x = 2 \cos \theta \Rightarrow dx = -2 \sin \theta d\theta$, so the measure is $\sin \theta dx = \sqrt{4 - x^2} dx$, i.e.,

$$d\mu(x) = \frac{1}{2\pi} \sqrt{4 - x^2} dx$$

is the orthogonality measure for this problem.

If $x \notin [-2, 2]$ ($x \in \mathbb{C}$), $e^{\pm i\theta}$ have different rates of growth so one dominates for $\sin(n+1)\theta/\sin\theta$ for n large, i.e.,

$$|p_n(x)| \sim \left| \frac{x}{2} + \sqrt{1 - \left(\frac{x}{2}\right)^2} \right|^n \rightarrow 1$$

as $n \rightarrow \infty$. $x \notin [-2, 2]$ is critical to avoid oscillation.

There is a branch of $\sqrt{\quad}$ so $|\dots| > 1$ on $\mathbb{C} \setminus [-2, 2]$.

One question we'll answer is where $\frac{x}{2} + \sqrt{1 - \left(\frac{x}{2}\right)^2}$ comes from.

What does it mean to say that a sequence, $y_n \sim a^n$ for n large?

Root asymptotics: $|y_n|^{1/n} \rightarrow |a|$.

Ratio asymptotics: $\frac{y_{n+1}}{y_n} \rightarrow a$.

Szegő asymptotics: $y_n/Aa^n \rightarrow 1$ for some A .

A second theme in this pair of lectures will be to explore when these conditions hold for OPUC/OPRL close to the “free” case ($\alpha_n \equiv 0$ for OPUC; $a_n \equiv 1, b_n \equiv 0$ for OPRL).

We’ll look at this asymptotics away from $\text{supp}(d\mu)$ because on $\text{supp}(d\mu)$, the asymptotics are typically unusual (decay rather than growth for isolated points in $\text{supp}(d\mu)$; oscillation on the a.c. part of $d\mu$.)

That said, asymptotic behavior on the spectrum can have important consequences as we’ll illustrate with the theory of L^1 perturbations.

OPUC Transfer Matrices

We begin by looking at all solutions of the difference equations that describe recursion. In some sense, they are both second order, so there is a 2×2 “update” matrix that takes data at $n = 0$ to data at $n = m$.

For OPUC, we saw that $A(z; \alpha_n) \begin{pmatrix} \varphi_n \\ \varphi_n^* \end{pmatrix} = \begin{pmatrix} \varphi_{n+1} \\ \varphi_{n+1}^* \end{pmatrix}$

$$A(z; \alpha) = \rho^{-1} \begin{pmatrix} z & -\bar{\alpha} \\ -\alpha z & 1 \end{pmatrix}$$

Notice that $\det A(z; \alpha) = z$, so for $z \neq 0$, $z \in \mathbb{C}$, we have A invertible and for $z \in \partial\mathbb{D}$,

$$\|A^{-1}\| = \|A\|$$

Define the transfer matrix by

$$T_n(z; \alpha_{n-1}, \dots, \alpha_0) = A(z; \alpha_{n-1}) A(z; \alpha_{n-2}) \cdots A(z; \alpha_0)$$

Thus,
$$\begin{pmatrix} \varphi_n \\ \varphi_n^* \end{pmatrix} = T_n \begin{pmatrix} 1 \\ 1 \end{pmatrix}$$

The second kind of polynomials are defined by

$$\begin{pmatrix} \psi_n \\ -\psi_n^* \end{pmatrix} = T_n \begin{pmatrix} 1 \\ -1 \end{pmatrix}$$

A little thought using

$$\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} A(z; \alpha) \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} = A(z; -\alpha)$$

shows that

$$\psi_n(z; \{\alpha_j\}_{j=0}^{n-1}) = \varphi_n(z; \{-\alpha_j\}_{j=0}^{n-1})$$

OPUC L^1 Perturbation

As a simple application of transfer matrices for OPUC, we prove

Theorem. *If*

$$\sum_{j=0}^{\infty} |\alpha_j| < \infty$$

then $d\mu = w(\theta) \frac{d\theta}{2\pi}$ with $\inf w > 0$, $\text{supp } w < \infty$ (so $d\mu_s = 0$).

Remarks. 1. Our proof can be slightly extended to show w is continuous.

2. A much stronger result is known (Baxter's Theorem):

$\sum_{j=0}^{\infty} |\alpha_j(d\mu)| < \infty \Leftrightarrow \sum_{j=0}^{\infty} |c_j(d\mu)| < \infty + (d\mu = w(\theta) \frac{d\theta}{2\pi}, w \text{ continuous with } \inf w > 0.)$

OPUC L^1 Perturbation

Notice that for $|z| = 1$, we have that (Euclidean norm on \mathbb{C}^2)

$$\|A(z; \alpha)\| \leq 1 + |\alpha| \leq e^{|\alpha|}$$

Thus, $\|T_n(z; \alpha_0, \dots, \alpha_{n-1})\| \leq e^{\sum_0^{n-1} |\alpha_j|}$

so $\sup_{|z|=1, n} |\varphi_n(t)| \leq e^{\sum_0^{\infty} |\alpha_j|}$

but $\|A^{-1}\| = \|A\|$ for $|z| = 1$ and $|\varphi| = |\varphi^*|$

implies $\inf_{|z|=1, n} |\varphi_n(t)| \geq e^{-\sum_0^{\infty} |\alpha_j|}$

Thus, by Bernstein–Szegő, we get the desired result.

Consider the difference equation

$$u_{n+1} = a_n^{-1}((z - b_n)u_n - a_{n-1}u_{n-1})$$

$u_n = p_{n-1}(z)$ solves this equation with $u_0 = 0$, $u_1 = 1$.

The difference equation can be rewritten (we take $a_0 = 1$)

$$\begin{pmatrix} u_{n+1} \\ a_n u_n \end{pmatrix} = A(z; a_n, b_n) \begin{pmatrix} u_n \\ a_{n-1} u_{n-1} \end{pmatrix};$$

$$A(z; a, b) = \frac{1}{a} \begin{pmatrix} z - b & -1 \\ a^2 & 0 \end{pmatrix}$$

The reason for the funny a_n in the lower component (a suggestion of Killip) is that it makes

$$\det A = 1$$

This implies if u, v are two solutions (same z) that (courtesy of Wronkian) $a_n(u_{n+1}v_n - u_nv_{n+1}) = \text{constant}$.

As for OPUC, we define

$$T_n(z; \{a_j, b_j\}_{j=1}^n) = A(z; a_n, b_n) \cdots A(z; a_1, b_1) \text{ so}$$

$$T_n \begin{pmatrix} 1 \\ 0 \end{pmatrix} = \begin{pmatrix} p_n(z) \\ a_n p_{n-1}(z) \end{pmatrix}$$

In the free Jacobi matrix case,

$$A_0(z) = \begin{pmatrix} z & -1 \\ 1 & 0 \end{pmatrix}$$

Since $\|A_0(z)\begin{pmatrix} 1 \\ 0 \end{pmatrix}\| = \|\begin{pmatrix} z \\ 1 \end{pmatrix}\| = 1 + |z|^2$, except for $z = 0$, $A_0(z)$ is not a contraction in the Euclidean norm. Since (as we'll see) $\sup_n \|A_0(z)^n\|$ is bounded for $z \in (-2, 2)$, this isn't a problem for A_0 but it makes perturbations tricky.

We'll overcome this by changing norm. In essence, the plane wave solutions will be a basis, so this is essentially a variation of parameters argument.

We are heading towards a proof of

Theorem. Let $\{a_n, b_n\}_{n=1}^{\infty} \subset [(0, \infty) \times \mathbb{R}]^{\infty}$ obey

$$\sum_{n=1}^{\infty} |a_n - 1| + |b_n| < \infty$$

Then, for any $\varepsilon > 0$, there is $C_{\varepsilon} > 0$ so that for all n and all $x \in [-2 + \varepsilon, 2 - \varepsilon]$, we have

$$C_{\varepsilon} \leq |p_n(x)|^2 + |p_{n-1}(x)|^2 \leq C_{\varepsilon}^{-1}$$

In particular (since $0 < \inf a_n < \sup a_n < \infty$), J has purely a.c. spectrum in $(-2, 2)$.

OPRL L^1 Perturbation

Since $\det A_0(2 \cos \theta) = 1$, $\text{Tr}(A_0(2 \cos \theta)) = 2 \cos \theta$, the eigenvalues of $A_0(2 \cos \theta)$ are $\pm e^{i\theta}$. Thus, for $x \in (-2, 2)$, there is $U(x)$ so

$$U(x) A_0(x) U(x)^{-1} = \begin{pmatrix} e^{i\theta(x)} & 0 \\ 0 & e^{-i\theta(x)} \end{pmatrix}$$

We define

$$\|B\|_x = \|U(x)BU(x)^{-1}\|$$

where $\|\cdot\|$ without an x is Euclidean norm. $\|\cdot\|_x$ is a Banach algebra norm on $\text{Hom}(\mathbb{C}^2)$, since

$$U(x)BCU(x)^{-1} = [U(x)BU(x)^{-1}][U(x)CU(x)^{-1}]$$

$U(x)$ is singular at $x = \pm 2$ but on $(-2, 2)$ it can be chosen real analytic (and, in particular, so $U(x)$ and $U(x)^{-1}$ are bounded on each $[-2 + \varepsilon, 2 - \varepsilon]$).

Thus, for each interval, there is $D_\varepsilon > 0$ so for all x in the interval and B

$$D_\varepsilon \|B\| \leq \|B\|_x \leq D_\varepsilon^{-1} \|B\|$$

The point, of course, is that $\|A_0(x)\|_x = 1$, so

$$\|a_n A_n(x; a_n, b_n)\|_x \leq 1 + E_x [\|a_n - 1\| + \|b_n\|]$$

Since $\delta \leq a_n \leq \delta^{-1}$ and $\sum_n |a_n - 1| < \infty$, $\prod_{j=1}^n a_j$ and its inverse converge and are uniformly bounded.

We conclude $\|T_n\|_x$ and $\|T_n^{-1}\|_x$ and so $\|T_n\|$ and $\|T_n^{-1}\|$ are uniformly bounded on $[-2 + \varepsilon, 2 + \varepsilon]$ which yields the claimed estimates.

Szegő Asymptotics for OPUC

For OPUC, the condition for $d\mu = f(\theta) \frac{d\theta}{2\pi} + d\mu_s$

$$\int \log f(\theta) \frac{d\theta}{2\pi} > -\infty$$

is called the Szegő condition. When it holds, we define the Szegő function, $D(z)$, on \mathbb{D} by

$$D(z) = \exp\left(\int \frac{e^{i\theta} + z}{e^{i\theta} - z} \log(f(\theta)) \frac{d\theta}{4\pi}\right)$$

Lemma. *If the Szegő condition holds, $D \in H^2(\mathbb{D})$, indeed,*

$$\sup_{0 \leq r < 1} \int |D(re^{i\theta})|^2 \frac{d\theta}{2\pi} \leq 1$$

and, with $D(e^{i\theta}) \equiv \lim_{r \uparrow 1} D(re^{i\theta})$,

$$|D(e^{i\theta})|^2 = f(\theta)$$

Chebyshev Asym

Three Asym

Regular Measures

Ratio Asym

Szegő Asymptotics for OPUC

Proof. Let $f_\varepsilon(\theta) = \min(f(\theta), \varepsilon^{-1})$. Then $\log(f_\varepsilon(\theta))$ is bounded above by $\log(\varepsilon^{-1})$, so

$$\operatorname{Re} \left(\int \frac{e^{i\theta} + z}{e^{i\theta} - z} \log(f_\varepsilon(\theta)) \frac{d\theta}{4\pi} \right) \leq \frac{1}{2} \log(\varepsilon^{-1})$$

so $|D_\varepsilon| \leq \varepsilon^{-1/2}$. Thus, D_ε lies in H^∞ and has boundary values

$$|D_\varepsilon(e^{i\theta})|^2 = f_\varepsilon(\theta)$$

Therefore, $D_\varepsilon \in H^2$ and

$$\sup_{0 \leq r < 1} \int |D_\varepsilon(re^{i\theta})|^2 \frac{d\theta}{2\pi} = \int |D_\varepsilon(e^{i\theta})|^2 \frac{d\theta}{2\pi} \leq 1$$

Taking $\varepsilon \downarrow 0$, we see that $D \in H^2$ and the rest follows.

Since $\text{RHS} \rightarrow 0$ as $n \rightarrow \infty$ (if the product converges, i.e., if the Szegő condition holds), each term goes to zero.

Thus $\int |\varphi_n^*(e^{i\theta})|^2 d\mu_s \rightarrow 0$ and $\varphi_n^* D \rightarrow 1$ in $L^2(\partial\mathbb{D}, \frac{d\theta}{2\pi})$.

Since the Poisson kernel $P_z(e^{i\theta})$ is L^2 uniformly for $|z| \leq r < 1$, $\varphi_n^*(z) D(z) \rightarrow 1$ uniformly on $|z| \leq r < 1$.

Thus, uniformly in $|z| \geq r^{-1} > 1$,

$$z^{-n} \varphi_n(z) \rightarrow \left[\overline{D\left(\frac{1}{z}\right)} \right]^{-1}$$

which is Szegő asymptotics for φ_n .

One also finds (Section 13.1 and 13.2 of [OPUC2] have two different proofs)—known as Geronimus relations

$$a_{n+1}^2 = (1 - \alpha_{2n-1})(1 - \alpha_{2n}^2)(1 + \alpha_{2n+1})$$

$$b_{n+1} = (1 - \alpha_{2n-1})\alpha_{2n} - (1 + \alpha_{2n-1})\alpha_{2n-2}$$

Szegő Asymptotics for $[-2, 2]$

From $a_n^2 \cdots a_1^2 = 2(1 + \alpha_{2n-1}) \prod_{j=0}^{2n-1} (1 - \alpha_j^2)$, one sees

$$\sum_{j=1}^{\infty} |\alpha_j|^2 < \infty \Leftrightarrow \limsup a_1 \cdots a_n > 0$$

This leads to

Shohat–Nevai Theorem. Let $d\mu = f(x) dx + d\mu_s$ be supported on $[-2, 2]$. Then

$$\limsup a_1 \cdots a_n > 0 \Leftrightarrow \int_{-2}^2 (4-x^2)^{-1/2} \log(f(x)) dx > -\infty$$

If that holds, then

$$\sum_{n=1}^{\infty} (a_n - 1)^2 + b_n^2 < \infty, \quad \lim a_1 \cdots a_N,$$

$$\lim \sum_{n=1}^N (a_n - 1) \text{ and } \lim \sum_{n=1}^N b_n \text{ all exist.}$$

It is critical that we require that $\text{support}(d\mu) \subset [-2, 2]$, i.e., no eigenvalues outside $[-2, 2]$ —unnatural from perturbation theory point of view.

$\int_{-2}^2 (4 - x^2)^{-1/2} \log(f(x)) dx > -\infty$ is called *the Szegő condition*.

$$x = 2 \cos \theta \Rightarrow dx = -2 \sin \theta d\theta \Rightarrow d\theta = \frac{dx}{-2 \sin(\theta)}$$

$$\Rightarrow d\theta = (4 - x^2)^{-1/2} dx.$$

The other relations follow from Geronimus relations.

Recall that

$$P_n\left(z + \frac{1}{z}\right) = \left[1 - \alpha_{2n-1}(d\mu)\right]^{-1} z^{-n} \left[\Phi_{2n}(z) + \Phi_{2n}^*(z)\right]$$

and for $|z| > 1$,

$$z^{-2n} \Phi_{2n}(z) \rightarrow \overline{D(0)/D\left(\frac{1}{z}\right)}$$

By the maximum principle $(1 + \varepsilon)^{-2n} \Phi_{2n}(z) \rightarrow 0$ for $|z| > 1$, so $z^{-2n} \Phi_{2n}^*(z) \rightarrow 0$.

Thus, we obtain

Theorem (Szegő asymptotics for $[-2, 2]$, with no bound states). *If the Szegő condition holds, then, for $|z| > 1$*

$$z^{-n} P_n(z + \frac{1}{z}) \rightarrow G(z) \equiv [1 - \alpha_{2n-1}(d\mu)]^{-1} \overline{D(0)/D(\frac{1}{z})}$$

Equivalently, for $x \in \mathbb{C} \setminus [-2, 2]$

$$\left(\frac{x}{2} + \sqrt{\left(\frac{x}{2}\right)^2 - 1}\right)^{-n} P_n(x) \rightarrow \tilde{G}(x)$$

The Density of Zeros

I now say a little about root and ratio asymptotics. In the final lectures, I hope to return to this subject.

As a warm-up for root asymptotics, let J_N be the $N \times N$ truncated Jacobi matrix (with b_1, \dots, b_n along the diagonal). Let $D_n(z) = \det(z - J_N)$. Then, expanding in minors:

$$D_N = -a_{N-1}^2 D_{N-2} + (z - b_N) D_{N-1}; \quad D_0 = 1, D_{-1} = 0$$

Thus $D_N(z) = P_N(z)$.

which implies zero of $P_N =$ eigenvalues of J_N are real and simple.

The Density of Zeros

For each N , let $x_1^{(N)} < \dots < x_N^{(N)}$ be the zeros. By the variational principle, $x_j^{(N)} < x_j^{(N+1)} < x_{j+1}^{(N+1)}$, i.e., zero interlace. Let

$$\nu^{(N)} = \frac{1}{N} \sum_{j=1}^N \delta_{x_j^{(N)}}$$

If

$$\nu = \text{w-lim } \nu^{(N)}$$

exists, we say ν is the density of zeros, aka, density of states.

ν is boundary condition independent, e.g., if

$$J_N^{\text{per}} = \begin{pmatrix} b_1 & \dots & a_N e^{i\theta} \\ \vdots & \ddots & \vdots \\ a_N e^{-i\theta} & \dots & b_N \end{pmatrix}$$

$$\text{w-lim } \nu_{\text{per}}^{(N)} = \text{w-lim } \nu^{(N)}$$

For

$$\int x^\ell d\nu(x) = \lim_{N \rightarrow \infty} \frac{1}{N} \text{Tr}(J_n^\ell)$$

and $|\text{Tr}(J_N^\ell) - \text{Tr}((J_N^{\text{per}})^\ell)|$ is bounded.

Thouless Formula

The DOS is intimately connected to root asymptotics because

$$p_n(z) = (a_1 \cdots a_n)^{-1} \prod_{j=1}^N (z - x_j^{(n)})$$

so

$$\frac{1}{n} \log |p_n(z)| = -\frac{1}{n} \log (a_1 \cdots a_n) + \int \log |z - x| d\nu^{(N)}(x)$$

Theorem (Thouless Formula). If DOS exists and

$$\lim (a_1 \cdots a_n)^{1/n} = c(d\mu)$$

exists, then for $z \in \mathbb{C} \setminus \mathbb{R}$, $(\Phi_\mu(z) = \int \log |z - x|^{-1} d\mu(x)$ is the potential of μ)

$$\lim \frac{1}{n} \log |p_n(z)| = -\log c(d\mu) + \int \log |z - x| d\nu(x)$$

Given any compact set, ϵ , we say ϵ has zero capacity if

$$\mathcal{E}(\mu) = \int d\mu(x) d\mu(y) \log |x - y|^{-1}$$

is infinite for all $\mu \in M_{+,1}(\epsilon)$.

(Note: the integral is either $+\infty$ or finite.)

If ϵ does not have zero capacity, we define $C(\epsilon)$ by

$$C(\epsilon) = \exp\left(-\inf_{\mu \in M_{+,1}(\epsilon)} \mathcal{E}(\mu)\right)$$

Connection to Potential Theory

It is a fundamental theorem that if $C(\epsilon) > 0$, there is a unique probability measure, ρ_ϵ , called the *equilibrium measure* or the *harmonic measure* for ϵ with $\mathcal{E}(\rho_\epsilon) = \inf \mathcal{E}(\mu)$.

$T_{n,\epsilon}$, the Chebyshev polynomial for ϵ , is the (it turns out unique) monic polynomial of degree n with

$$\|T_{n,\epsilon}\|_{\infty,\epsilon} = \inf_{P \text{ monic}} \|P\|_{\infty,\epsilon}; \quad \|f\|_{\infty,\epsilon} = \sup_{x \in \epsilon} |f(x)|$$

Theorem (Faber–Fekete–Szegő).

$$\|T_n\|_{\infty,\epsilon}^{1/n} \geq C(\epsilon) \text{ and } \lim_{n \rightarrow \infty} \|T_n\|_{\infty,\epsilon}^{1/n} = C(\epsilon)$$

Regular Measures

Since $\|T_n\|_{L^2(d\mu)} \leq \|T_n\|_{\infty, \mathfrak{e}}$, if

$$\mathfrak{e} = \text{supp}(\mu)$$

and $\|P_n\|_{L^2(d\mu)} \leq \|T_n\|_{L^2(d\mu)}$ (by variational principle)

$$\limsup (a_1 \cdots a_n)^{1/n} \leq C(\mathfrak{e}).$$

We call μ regular (with $\text{supp}(\mu) = \mathfrak{e} \subset \mathbb{R}$) if

$$\lim_{n \rightarrow \infty} (a_1 \cdots a_n)^{1/n} = C(\mathfrak{e}).$$

Pioneers are Ulmann (for $\mathfrak{e} = [0, 1]$) and Stahl–Totik ($\mathfrak{e} \in \mathbb{C}$).

If μ is regular, the DOS exists and equals the equilibrium measure for ϵ .

Thus, for $z \in \mathbb{C} \setminus \mathbb{R}$, $\lim_{n \rightarrow \infty} |p_n(z)|^{1/n} = e^{G_\epsilon(z)}$.

$$G_\epsilon(z) = \log (C(\epsilon))^{-1} - \Phi_{\rho_\epsilon}(z)$$

This is the potential theorists' Green's Function, the unique function subharmonic on \mathbb{C} , harmonic on $\mathbb{C} \setminus \epsilon$, equal to 0 q.e. on ϵ and $\log(|z|) + O(1)$ at ∞ .

Szegő's Asymptotic Theorem for OPUC says $\Phi_n^*(z) \rightarrow D(0)D(z)^{-1}$ as $n \rightarrow \infty$ so $\Phi_{n+1}^*/\Phi_n^* \rightarrow 1$. We state without proof

Krushchev's Theorem (see [OPUC2], Section 9.5).

$\Phi_{n+1}^*(z)/\Phi_n^*(z)$ converges uniformly on each $\{z \mid |z| < 1 - \varepsilon\}$ if and only if either

For $\ell = 1, 2, \dots$, $\lim_{n \rightarrow \infty} \alpha_{n+\ell} \alpha_n = 0$; limit is then 1.

OR $\exists a \in (0, 1]$ and $\lambda \in \partial\mathbb{D}$ so $\lim_{n \rightarrow \infty} |\alpha_n| = 0$,
 $\lim_{n \rightarrow \infty} \bar{\alpha}_{n+1} \alpha_n = a^2 \lambda$

and then limit $\frac{1}{2} \left[(1 + \lambda z) + \sqrt{(1 - z\lambda)^2 + 4a^2 \lambda z} \right]$.

Ratio Asymptotics

For OPRL, we have

Simon's Theorem (*J. Approx. Th.* **128** (2004), 198–217).

For OPRL if $\lim_{n \rightarrow \infty} \frac{P_{n+1}(z)}{P_n(z)}$ exists at a single point in $\mathbb{C} \setminus \mathbb{R}$, it exists at all points and this happens if and only if for some $a \in [0, \infty)$, $b \in \mathbb{R}$

$$\lim_{n \rightarrow \infty} a_n = a, \quad \lim_{n \rightarrow \infty} b_n = b$$

and the limit is

$$\frac{1}{2} \left[(z-b) + \sqrt{(z-b)^2 - 4a^2} \right] \quad (\text{root with } \sqrt{} = z \text{ near } \infty)$$

Closely related to ratio asymptotics (because the conclusions imply ratio asymptotics) are

Rakhmanov's Theorem. *If $d\mu = f(\theta) \frac{d\theta}{2\pi} + d\mu_s$ and $f(\theta) > 0$ for a.e. θ , then $\alpha_n \rightarrow 0$.*

Denisov–Rakhmanov Theorem. *If $d\mu = f(x) dx + d\mu_z$ and $f(x) > 0$ on $[-2, 2)$ and $\sigma_{(\text{ess})}(J) = [-2, 2]$, then $a_n \rightarrow 1$, $b_n \rightarrow 0$.*

I hope to say more about this in Lecture 11 or 12.

Moral is ratio and Szegő asymptotics unusual. Expect oscillations.
